R-Machine is the Solution to PC troubles. The man accused of placing a noose in a Portland, Ore., library has been charged with first-degree intimidation and failure to discharge the duties of a public servant, Portland police said. Police said in a press release that an officer responded to the Northwest Library's reference desk at about 2:40 p.m. Saturday afternoon, and the man was asked to leave. "During the interaction, the man allegedly asked to use the library's phone," the release said. "The officer said he would be required to provide identification and the man said he was not going to give his name." The phone call was placed to a crisis call center, police said. After the call, the man went to the library's restroom, where he placed the noose in the urinal, police said. Later, the man was seen standing over the urinal in the library's men's bathroom, police said. The man became upset when he was confronted by a library employee and police officers and refused to speak to officers, police said. The man was arrested, and no photo of the man was released at the time. The man was taken into custody, and was booked on suspicion of first-degree intimidation and failure to discharge the duties of a public servant, police said. His name was not released. —Jayati Ramakrishnan; 503-221-4320; jramakrishnan@oregonian.com; @JRamakrishnanOR Visit subscription.oregonlive.com/newsletters to get Oregonian/OregonLive journalism delivered to your email inbox. After a thrilling contest with the Bulldogs last week, the Mariners head to work again this weekend

Q: Predicting the occurrence of certain words on a web page I am making a web application that needs to process each line of a web page content asynchronously. Each line is parsed and then a function is called to predict the occurrence of a certain set of words, e.g. all words that start with A in the example below. The prediction function should take into account information from other lines, and should be able to predict the occurrence of a word that have not yet been parsed. In this example, I have 4 lines, so "A01" would be parsed on the line 1. "A01" would be predicted as a false. It does not exist in line 4. "A02" is a word that start with A on line 2. So it is

predicted as true on line 3, because line 2 says true. "A03" would be predicted as true on line 3, because line 2 says true. "A04" would be predicted as true on line 4, because it is also true on line 3. Given the same data, but with 5 lines, "A01" would be predicted as false. "A02" would be predicted as true on line 3, because line 2 says true. "A03" would be predicted as false on line 4, because it exists on line 3. "A04" would be predicted as false on line 3, because it exists on line 2. "A05" would be predicted as false on line 3, because it does not exist on line 2. What I would like to achieve is that given a document with unknown length, the prediction would be made on the first line to be parsed. So, if I have only 2 lines, I would like "A01" to be

predicted as false on line 2, and then, if it does not exist on line 3, to be predicted as false on line 3. I guess this is a pretty common problem and I have seen stuff about it, but the only way to describe it was through a literal Google search. I am looking for some algorithms or methods that can do this efficiently, or maybe a better word I can use to describe it. A: You can try with a very f678ea9f9e
